@digininja

# From the UK

# Qualifications for this talk

- Started work as desktop app developer in 1996
- Moved to web app in 2003
- Now a tester but still do bits on the site
- Published over 50 security tools

# The Theory

The potentially patronising\* bit

\*patronizing

<https://digi.ninja>

# Variables

# Main Types

Strings – “hello”, ‘world’, “1234”, “this is it”

Integers – 42, -1, 9223372036854775807\*

Floats – 3.1415, 42.42, -57.4, 10.0

Arrays/Lists – [ 3, “aa”, 5.7, ‘hello’ ]

Objects – car.no\_of\_wheels, fruit.colour\*\*

\* Technically a Long but you get the idea    \*\* color

<https://digi.ninja>

# Assigning

```
$number = 42
```

```
my_string = "hello"
```

```
var aFloat = 3.14
```

```
int i
```

```
i = 27
```

# Conditionals

# Equality

== usually means “is this equal to?”

```
if my_number == 27  
    print “x equals 27”
```

```
if message == “hello”  
    print “He said hello”
```

# Equality Gotcha

Remember from variables...

= usually means “becomes equal to”

```
if x = 42
```

```
    print “x has now been assigned the value 42”
```

# Inequality

Is not equal to can sometimes be:

!= Or <>

```
if x != 10
```

```
    print "It isn't 10"
```

# Otherwise

```
if x = 10
```

```
    print "x is 10"
```

```
else
```

```
    print "x is not 10"
```

# Combined

```
if x == 10
    print "it is 10"
else
    if x != 20
        print "it isn't 20"
    else
        print "it must be 20"
```

Not the best  
way to do this!

# Maths\*

## Standard maths things

if  $x < 10$     if  $x$  is less than 10

if  $x \geq 10$     if  $x$  is 10 or greater

\* Math

<https://digi.ninja>

# Boolean Logic

if a=="hello" and b=="robin"

if username=="root" or uid==0

if count == 10 && time < 40 || hits > 7

# Brackets

To force order, use brackets.

These two statements mean different things:

if (x==10 and y==3) or (z==7)

if (x==10) and (y==3 or z==7)

# Proof

if (x==10 and y==3) or (z==7)

| x | y | z | res |

# Loops

# For Loops

Do this so many times

```
for i=1; i < 10; i = i + 1  
  print i
```

Shortcut  
 $i = i + 1$   
can often be written  
 $i++$  or  $i += 1$

Result:

1  
2  
3  
4  
5  
6  
7  
8  
9

# While Loops

Do this until criteria met

```
key = "n"
```

```
while key != "y"
```

```
    print "not yet"
```

```
    key = get_keypress()
```

```
print "done"
```

| Key | Result |
|-----|--------|
|-----|--------|

|   |         |
|---|---------|
| n | not yet |
|---|---------|

|   |         |
|---|---------|
| n | not yet |
|---|---------|

|   |      |
|---|------|
| y | done |
|---|------|

# Blocks

# Keyword/Symbol Delimited

```
if result == true then
```

```
    print "it worked"
```

```
    x = 32
```

```
    <more stuff here>
```

```
end
```

```
print "outside the block"
```

```
if result == true {
```

```
    print "it worked"
```

```
    x = 32
```

```
    <more stuff here>
```

```
}
```

```
print "outside the block"
```

# Whitespace Delimited

```
if result == true:
```

```
    print "it worked"
```

```
    if x == 32:
```

```
        print "and the answer was 32"
```

```
print "outside the block"
```

# Step Back – Delimited

```
if result == true then  
    print "it worked"
```

```
x = 32
```

```
    <more stuff here>
```

```
end
```

```
print "outside the block"
```

# Functions

# Group Code Together

- Like a block but can be reused
- Avoids repetition
- Saves effort
- Saves mistakes

# Parameters In

```
function saySomething (message, num) {  
    print "the message is: " + message  
    print "double the number is: "  
    print num * 2  
}  
  
saySomething ("hello", 7)
```

# Parameters Out

```
function invert_evens (number) {  
    if number % 2 == 0  
        return (number * -1)  
    return number  
}
```

```
neg = invert_evens (1471)
```
